Bacterial Recombination

- ▶ Bacteria reproduce clonally via binary fission.
- ▶ Multiple mechanisms allow for non-vertical transfer of genetic information:
 - ▶ Conjugation
 - ▶ Natural transformation
 - ▶ Phage-mediated transduction
- ▶ The frequency at which these events occur depends on the bacterial species (i.e. depends on the genome: a strange loop!)
- ▶ The effect of these events can be:
 - ▶ Plasmid transfer
 - ▶ Insertion
 - ▶ Homologous recombination
- ▶ Focus solely on homologous recombination: only event which doesn't alter the length of the sequence.

The Problem for Phylogenetic Inference

For many bacteria, the ratio between the recombination rate and the mutation rate is very high.

Problem

The space of possible ancestral recombination graphs is extremely large. Even two samples have infinitely many distinct ancestries!

Approximation 1: ClonalFrame

Approximation 2: ClonalOrigin

Didelot et al. (2010)

Inference under the ClonalOrigin model

Inference follows the standard Bayesian phylogenetic tradition:

$$f(\mathbf{G}, \mathbf{N}, \boldsymbol{\mu}, \rho, \delta | \mathbf{A}) \propto P_{\mathbf{F}}(\mathbf{A} | \mathbf{G}, \boldsymbol{\mu}) f_{\text{CGC}}(\mathbf{G} | \mathbf{N}, \rho, \delta) f_{\text{prior}}(\mathbf{N}, \boldsymbol{\mu}, \rho, \delta)$$

where

\mathbf{A} is the sequence alignment,

$\boldsymbol{\mu}$ are the substitution model parameters, and

\mathbf{G} is the full sample genealogy including clonal frame \mathbf{T} and M conversions $\{\mathbf{C}_i\}_{i \in [1 \dots M]}$.

The genealogy density under ClonalOrigin model can be expanded

$$f_{\text{CGC}}(\mathbf{G} | \rho', \delta, \mathbf{N}) = \left(\prod_{i=1}^M f(\mathbf{C}_i | \mathbf{T}, \mathbf{N}, \delta) \right) P(M | \mathbf{T}, \rho) f_{\mathbf{C}}(\mathbf{T} | \mathbf{N})$$

Identifiability

Despite using a simplified model, an infinite number of ARGs still possess the same likelihood given a sequence alignment.

Very important for an MCMC algorithm to propose state changes which minimize effect on likelihood.

ClonalOrigin in BEAST

- ▶ BEAST package that performs inference under the ClonalOrigin model.
- ▶ Joint inference of clonal frame and recombinant edges.
- ▶ Can be combined with usual variety of substitution models and parametric population models.
- ▶ Straight-forward usage via BEAUti.

Bacter limitations

- ▶ Computational complexity scales with the number of proposed conversions.
 - ▶ This can be huge, even for small sample sets!
 - ▶ Can't use BEAGLE to speed things up: doesn't perform well due to peculiarities of ARG likelihood computation.
- ▶ MCMC algorithm used does not intelligently locate conversions.
 - ▶ Looking at fixing this in the near future.
- ▶ Summary algorithm can produce peculiar results.
 - ▶ More research needs to be done to find a better algorithm.

Bacterial phylogenetics in BEAST 2

[Installation & Usage Tutorial](#)[Source Code](#)

Bacter is a [BEAST 2](#) package which facilitates joint Bayesian inference of ancestral recombination graphs (ARG) and related parameters from bacterial sequence alignments under the [ClonalOrigin](#) model.

ARGs

Bacter allows you to infer the ARG that gave rise to your sampled data, including both clonal frame and the recombinant edges. Loci and sites affected by each conversion are also inferred.

Parameters

For informative data sets, Bacter can sample posterior distributions for parameters such as the recombination rate and expected converted tract length jointly with the ARG. For serially sampled data, joint estimation of the molecular clock rate is also possible.

Population dynamics

Bacter includes support for producing Bayesian Skyline Plot (BSP) inferences of bacterial population dynamics. This inference may actually be more powerful when recombination is present in your data set.
